Assignment 2 – House Prices Analysis Final Report

Summary

Performed an Exploratory Data Analysis (EDA) on the House Prices Dataset, focusing on three hypotheses to explore what factors drive house prices up or down.

Hypothesis 1 – Build Year and Sale Price

Overall, sale prices show a strong positive trend based on the year built, with property values rising significantly for homes built after the 1980s. Additionally, the high price spikes seen between 1880 and 1900 were caused by small sample sizes rather than a real market trend.

Hypothesis 2 – Living Area and Sale Price

The scatter plot confirms a positive relationship between square footage and price—larger homes generally cost more. Moreover, the visual analysis highlights a few unusual outliers in the lower-right section (properties over 4,000 sq ft that sold for under $200,000). Checking the data directly shows that these outliers had a SaleCondition of Partial, meaning they were partial or incomplete sales rather than normal market deals.

Hypothesis 3 – House Style and Sale Price

Multi-story homes like 2Story and 2.5Fin tend to have higher average sale prices, which reflects buyer preference for more usable layout space. Interestingly, 1Story homes also rank high in price, while 1.5-story homes are generally more reasonably priced.
